Teething Symptoms and Home Remedies

Many pediatricians, scientists, researchers and parents have disagreed about the concept of teething, but any mother of a little one will tell you that whether or not it's just a coincidence their babies are miserable when their teeth start coming in.

Teething 101

When newborns are born they have "teeth buds" just under the gums, and while there is no set time that those teeth will begin to appear, typically their first tooth will begin to break through between five and seven months. Some infants can begin teething as early as 3 months and some as late as 9 months to even a year.

Typically the incisors (top and bottom middle teeth) appear between the ages of six to seven months. Between the ages of 7 to 9 months the incisors will come in on each side of those first teeth that appeared. Around 12 months, a baby may have 8 teeth. The first molars will break through at 10 to 14 months. The canines appear at 16 months. Finally, the second molars will come in between 24 months to 30 months.

Teething Symptoms

Many experts disagree about whether or not teething even has symptoms. Most parents report unique changes prior to the appearance of their child's teeth. For instance, when a baby is teething their saliva production increases. This has caused many symptoms including drooling, which can sometimes cause a rash on their chin, coughing or gagging on the excess saliva and loose bowels due to swallowing that excess saliva.

Additional teething symptoms can be irritability or a desire to gnaw on anything within grasp. The pressure of the tooth trying to break through the gums can cause discomfort leading to irritability. Many babies instinctively reach for something to gnaw on as pressure on the gums will sometimes counteract the pressure caused by the teeth.

Misdiagnosing Teething

Most problematic for young parents is that teething symptoms may very often be mistaken for common childhood disorders. Pain from the gums can travel to the cheek and even the ear causing an infant to rub their cheek

or tug on their ear. Many young parents are taught to watch for this as a sign of an ear infection and so, in response, a parent will take their child to their pediatrician. The problem is that an irritable, teething infant will probably have been crying as well which, combined with the effects of teething, can lead to red ear, commonly leading to a misdiagnosis of Otitis Media and an unnecessary prescription for antibiotics.

It is very important as a parent to not be quick to accept this diagnosis. Even the American Academy of Pediatrics (AAP) set new guidelines in 2013 to regulate overly-prescribed antibiotics in the treatment of Otitis Media, having found that prescriptions were being written when they were not necessary.

The AAP suggests waiting 72-hours before giving a child antibiotics. Typically it can be fluid behind the ear (or teething symptoms) can be a false diagnosis. Whether you to avoid unnecessary antibiotic prescription is to require a culture. The only way to confirm Otitis Media is with a culture.

Many experts actually disagree about whether or not teething even has symptoms..."

Common Cold or Cutting Teeth

Another common childhood disorder confused with teething is the common cold. Since teething can lead to runny nose, mild/low-grade fever and coughing or sneezing, many infants have been treated for a cold or allergies when it was nothing more than a breaking or cutting tooth.

It's important to realize that our bodies were designed to do things in a certain way and not everything needs to be treated medically.

Over-the-Counter

Recognizing that there really isn't anything that can be done medically is little comfort to a parent who is dealing with a fussy, cranky, miserable little baby. Knowing what to

do to ease their discomfort and relieve some of the pain is empowering to a concerned parent potentially feeling powerless.

The first thing to understand is that there are natural, holistic choices, and it is never going to be necessary to resort to pain relievers or gum-numbing agents. These items can actually do more harm than good, and aspirin should never be given to a baby even to rub on their gums, as it has been linked with the potentially deadly disease, Reye's Syndrome.

Acetaminophen should also never be used, as the long-term effects of the chemicals in pain relievers on infants have not been recorded.

With regards to gum-numbing agents, while they have been found to be effective, it may be potentially dangerous. Popular pediatrician, Dr. Sears says on his website, "We do not recommend commercial gum-numbing substances because it is difficult to learn their exact composition. Research that validates their safety is limited."

Alternative Remedies

The only way to counter-act the pain of teething is with natural, holistic remedies. Dr. Sears says, "Desired relief can be achieved by using natural remedies to soothe symptoms, such as teething tablets in the mouth and natural relief of pain. Additionally, there are many natural remedies that can help relieve pressure, pain, and discomfort."

The first thing to understand is that the baby's gums are sore and aching. A sharp tooth is trying to push through the gums and this is what is causing the discomfort and resultant fussiness. Anything that will counter-balance that pressure is going to bring relief.

Many parents have reported that a clean wet washcloth put in the freezer for a short time, then given to the baby to gnaw on brings welcome relief. The cloth can be dipped in water or strong chamomile tea. The choice of tea adds a calming agent and is soothing to an infant's tummy. Similarly, a frozen banana given to the baby will give them something natural to gnaw on. Any item that might be used by the parent should be monitored to not be so small that the child could choke on.

Ice in a sandwich bag, then wrapped in a cloth works well, and for the older child already eating solid foods, cold soft foods such as applesauce or diced papaya can bring relief.

Other Home Remedies

Although in Europe the use of an Amber teething necklace has been reported to be effective, some more recent research in North America has indicated that the use of amber teething necklaces is touted to have no real effect, and may be harmful to the child.

Febrile (feverish) medicinal herbs such as chamomile, valerian, and other natural remedies are used for teething. Calceolaria for sudden fever, calcarea carbonica for teething in very young babies, especially while nursing or breastfeeding, and sleep, calcarea phosphorica for delayed teething and chamomilla for swollen, inflamed and tender gums.

The Chiropractic Factor

It's important to not interfere with the natural routine of teething. Every child is different, but teething has been proven to be hereditary. If an infant's parents' first tooth appeared when they were three months, then it's safe to assume this will be generational. It's not even unusual for a baby to be born with a tooth already in place. Recognizing the body's innate ability to work as it was designed, Family Wellness Chiropractors guide parents in natural ways to care for their children.

Dear Patient,
Dr. [YOUR NAME HERE] is dedicated to providing you with the absolute best in family wellness care. So take a moment today to discuss with your Family Wellness Chiropractor any concerns you may have regarding your family's overall health and wellness.
